Abstract – The cycloaddition reaction between 2,3-dimethylbuta-1,3-diene and 2-hydroxyethylmethacrylate proceeds by the second order kinetics. The rate constants increase with the increase in the excess of one of the reactants. The change in the effective rate constants is described by the Michaelis-Menten equation indicating that the reaction proceeds through the initial equilibrium stage of formation of an intermediate complex which then transforms into the product. The effective rate constants, the equilibrium constants of formation of the intermediate complex, and the rate constant of its transformation into the reaction product were determined, as well as the thermodynamic parameters of the formation of the intermediate complex and the activation parameters of the transformation of the intermediate complex into the product. The limiting stage of the reaction is established and its mechanism is suggested.

Key words — 2,3-dimethylbuta-1,3-diene, 2-hydroxyethylmethacrylate, 2-hydroxyethyl-1,3,4-trimethylcyclohex-3-ene-1-carboxylate, cycloaddition reaction, Michaelis—Menten equation, effective rate constants, intermediate complex, limiting stage.

#### I. Introduction

Alkylcyclohexene carboxylates are starting materials for drugs, as well as modifiers, plasticizers, epoxyresins, and co-monomers [1]. They are used to create lotions, body emulsions, shampoos, day and night creams, perfumes, and food flavors [2]. In this work we studied the kinetics of interaction between 2,3-dimethylbuta-1,3-diene (DMB) with 2-hydroxyethylmethacrylate (HEMA) to optimize the process of producing 2-hydroxyethyl-1,3,4-trimethylcyclohex-3-ene-1-carboxylate (1).

## II. Experiment

Kinetic studies were performed in temperature-controlled sealed glass ampules according to the method described in [3], in the temperature range 403-433K. To the 10 cm3 ampules were charged 2-hydroxyethylmethacrylate and 2,3-dimethylbuta-1,3-diene in the molar ratios from 1:1 to 1:1.75 and some hydroquinone, the ampules were sealed and placed in a thermostat. At

regular intervals, an ampule was removed from the thermostat, quickly cooled, opened, and the reaction mixture was analyzed by gas—liquid chromatography on a SELMI CHROM-1 apparatus. The quantitative analysis was performed with internal normalization. The accuracy of chromatographic analysis in multiple parallel determinations did not exceed 3% [4].

The investigated reaction proceeds according to the second-order kinetics. The values of effective rate constants are listed in Table 1. We found that the values of the effective secondorder constants increase with the increasing ratio 2,3-dimethylbuta-1,3-diene: 2-hydroxyethylmethacrylate. The difference is more pronounced at higher temperatures. It was appropriate to examine in more detail the mechanism of this reaction. Note that the mechanism of the [4 +2]-cycloaddition reaction today is still controversial [5].

Two concerted mechanism are suggested: a single-step (sinchronous) and a two-step, in which the first step is the limiting one [6]. The Arrhenius equation described satisfactorily the dependence of the effective rate constants on temperature for different ratios (Fig. 1), which allowed us the calculation of the formal activation energy and other activation parameters of the overall process (Table 1).

TABLE 1
EFFECTIVE RATE CONSTANTS AND ACTIVATION PARAMETERS OF
THE CYCLOADDITION REACTION BETWEEN 2,3-DIMETHYLBUTA1,3-DIENE AND 2-HYDROXYETHYLMETHACRYLATE

8	$(k_{eff}) \times 10^6$ , $1 \text{ mol}^{-1} \text{ s}^{-1}$						$K^{-1}$
HEMA : DMB	403K	413K	423K	433K	E <sub>eff</sub> , kJ mol <sup>-1</sup>	ΔH <sub>eff</sub> kJ mol <sup>-1</sup>	ΔS <sub>eff</sub> , J mol <sup>-1</sup> F
1:1	1.5	2.3	3.6	6.1	67.5	62.1	-181
1:1.25	1.7	3.0	4.7	7.3	70.0	63.7	-173
1:1.4	2.0	3.7	5.8	8.9	71.6	65.3	-168
1:1.5	2.2	4.2	6.9	10.1	73.7	67.0	-162
1:1.6	2.6	4.8	7.7	12.5	75.3	68.6	-157
1:1.75	3.1	6.0	9.8	15.2	76.4	70.3	-152

The correlation coefficient was satisfactory in all cases (R2 > 0.95). The analysis of the parameters maid it possible to establish that upon increase in the 2,3-dimethylbuta-1,3-diene excess and the accompanying increase in the values of keff a systematic increase was observed in the effective energy ( $\Delta$ Eeff) and the effective activation enthalpy ( $\Delta$ Heff). Simultaneously, the value of the effective activation entropy ( $\Delta$ Seff) also increased.

For all ratios of reagents an isokinetic relationship was observed with a high degree of correlation (R2 = 0.99) between the effective entropy and enthalpy of reaction, which allowed the calculation of the isokinetic temperature Tiso .= 287 K (Fig. 2) that was far from the investigated temperature range. The correlation coefficient was satisfactory in all cases (R2 > 0.95). The analysis of the parameters maid it possible to establish

that upon increase in the 2,3-dimethylbuta-1,3-diene excess and the accompanying increase in the values of keff a systematic increase was observed in the effective energy ( $\Delta$ Eeff) and the effective activation enthalpy ( $\Delta$ Heff). Simultaneously, the value of the effective activation entropy ( $\Delta$ Seff) also increased.

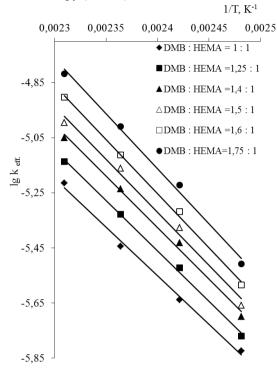

Fig. 1. Dependence of the effective rate constant of cycloaddition between 2,3-dimethylbuta-1,3-diene and 2-hydroxyethylmethacrylate on temperature for different ratios of reactants: 2,3-dimethylbuta-1,3-diene: 2-hydroxyethylmethacrylate

The increase in Eeff and ΔHeff with increasing excess of 2,3-dimethylbuta-1,3-diene and a simultaneous increase in ΔSeff indicate the increasing steric hindrances in the reaction course. This finding suggests also that the reaction mechanism is unique in the studied range of the reagents ratio. Such a systematic change in the rate constants with an increase in excess of one of the reactants is typical of the reactions that include the formation of the charge transfer complex (CTC by the reagents) [7, 8]. A similar reaction course has been proved also for several cases, including the alcoholysis of alcohols [9, 10], where the formation of charge-transfer complexes was confirmed by the methods of physicochemical and spectral analyses.

For these reactions the effective second-order rate constant does not remain constant at the change in the reagent ratio, and the kinetics of the process is described by the Michaelis–Menten equation:

A + B 
$$\xrightarrow{K_{eq}}$$
 [A : B]  $\xrightarrow{k_{conv}}$  Product
$$\frac{1}{k_{eff}} = \frac{1}{k_{conv}} - \frac{K_{eq}C_A}{k_{conv}}$$
(2)

where  $k_{eff}$  is experimentally determined effective second order rate constant (1 mol<sup>-1</sup> s<sup>-1</sup>) for each reagent ratio,

 $K_{eq}$  is the equilibrium constant (1 mol<sup>-1</sup>) for the intermediate complex formation,

 $k_{conv}$  is the rate constant (s<sup>-1</sup>) of the intermediate complex conversion into the reaction product,

C<sub>A</sub> is the molar concentration (M) of the substance taken in excess.

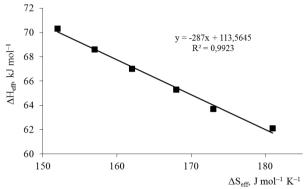

Fig. 2. Dependence of the effective activation entropy on the effective activation enthalpy of the cycloaddition between 2,3-dimethylbuta-1,3-diene and 2-hydroxyethylmethacrylate

#### III. Results and Discussion

In our case, the change in the effective rate constants of the 2,3-dimethylbuta-1,3-diene cycloaddition to 2-hydroxyethylmethacrylate as a dependence on the ratio of reactants is also satisfactorily described by the Michaelis–Menten equation (2). This fact suggests that the cycloaddition reaction between 2,3-dimethylbuta-1,3-diene and 2-hydroxyethylmethacrylate proceeds through a stage of equilibrium with the formation of an intermediate complex followed by its conversion into the reaction product [Eq. (3)].

From the dependences shown in Fig. 3 for four temperatures, we obtained the following linear equations:

$$403K: 1/k_{eff.} = -340146C_A + 838510, (R^2 = 0.998)$$
(4)
$$413K: 1/k_{eff.} = -244294C_A + 520041, (R^2 = 0.991)$$
(5)
$$423K: 1/k_{eff.} = -161490C_A + 338760, (R^2 = 0.994)$$
(6)
$$433K: 1/k_{eff.} = -94241C_A + 209279, (R^2 = 0.992)$$
(7)
$$\begin{pmatrix} CH_2 \\ CH_2 \end{pmatrix} + \begin{pmatrix} CH_2 \\ CH_2 \end{pmatrix} \begin{pmatrix} CH_2 \\ CH$$

The slope of the obtained straight lines gives the rate constants of the conversion of the intermediate complex in the reaction product ( $k_{conv}$ ). The values of the intercepts on the ordinate axis give the equilibrium constants of the complex formation (Table 2) according to the expression  $K_{eq} = 1/(k_{eff} \, k_{conv})$ .

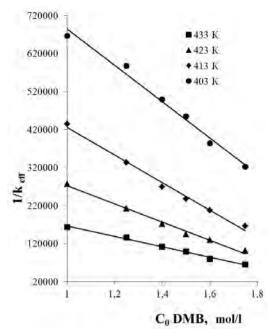

Fig. 3. Dependence of the effective rate constant of cycloaddition between 2,3-dimethylbuta-1,3-diene and 2-hydroxyethylmethacrylate on the C0 2,3-dimethylbuta-1,3-dien (DMB) in the temperature range 403-433K

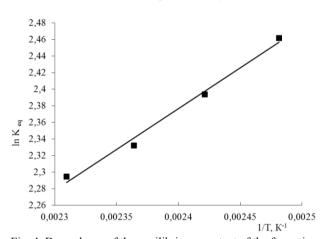

Fig. 4. Dependence of the equilibrium constant of the formation of intermediate complex on the temperature

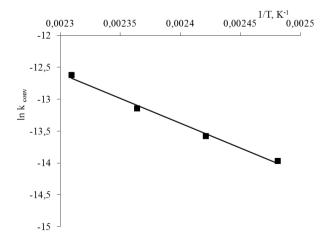

Fig. 5. Dependence of the rate constants of conversion of the intermediate complex in the reaction product on the temperature

The dependence of the equilibrium constant ( $K_{eq}$ ) of the intermediate complex formation is described by the isobar (Fig. 4,  $R^2 = 0.993$ ). The dependence of the rate constants of conversion ( $k_{conv}$ ) on temperature is described by the Arrhenius equation (Fig. 5,  $R^2 = 0.999$ ), which allows the calculation of the activation parameters of the intermediate complex conversion in the reaction product (Table 2).

#### TABLE 2

Equilibrium constants ( $K_{\rm EQ}$ ) and thermodynamic parameters of formation of the intermediate complex, the rate constants ( $K_{\rm CONV}$ ) and activation parameters of its transformation into a product

K <sub>eq</sub> ·10 <sup>2</sup> .					8.9	-242	85
K <sub>eq</sub> ·10 <sup>2</sup> , 1·mol <sup>-1</sup>	8.33	9.55	9.81	10.08	$\mathrm{E}_{\mathrm{conv}}$ , $\mathrm{kJ}~\mathrm{mol}^{-1}$	ΛΗ <sup>#</sup> <sub>conv</sub> , kJ mol <sup>-1</sup>	$\Delta S_{\mathrm{conv}}^{\#}$ , $\mathrm{J} \ \mathrm{mol}^{-1} \mathrm{K}^{-1}$ -
$K_{\text{conv}} \cdot 10^6, \text{ s}^-$	0.86	1.27	1.96	3.30	64.7	57.8	-193

The found positive  $\Delta Geq$  and negative  $\Delta Seq$  values indicate the energy advantage of the intermediate complex formation. At the same time a relatively fast decomposition of the intermediate complex suggests that its formation is the limiting stage of the process. Thus, we established for the first time that the kinetics of the investigated process obeyed Michaelis—Menten equation, which was valid in the case of the reaction course through the stage of the associative equilibrium. It is an argument in favor of this reaction to proceed by the mechanism of concerted cycloaddition. However, the nature of the interaction of the components should be studied in more detail

It is known that the addition of a diene molecule to the dienophile double bond originates from a certain deficiency of the electron density on this double bond due to its interactions with the other active groups, and the stronger conjugation with them, the easier the diene addition. Indeed, when keff of 2,3-dimethylbuta-1,3-diene interaction with 2-hydroxyethylmethacrylate at 353K is  $0.74\times10-6$  mol l–1 s–1 (determined graphically), the keff for the interaction of 2,3-dimethylbuta-1,3-diene with 1,4-naphthoquinone, where the  $\pi$ -bond interacts with two C=O groups, is  $0.14\times10-5$  mol l–1 s–1 (in hexane) [11], and with its 5-substituted derivatives it is even two orders of magnitude higher,  $1.5\times10-3$  mol l–1 s–1 [12]. The accelerating effect of electronegative substituents, like cyano group or halogen, on the cycloaddition reaction is

even more pronounced. Thus, in the interaction of cyclopentadiene with methyl acrylate at 303K in dioxane keff is 2.8×10–5 mol l–1 s–1, with fumaric acid dinitrile, 155×10–5 mol l–1 s–1, and with tetracyanoethylene, 10200×10–5 mol l–1 s–1. In such cases it is reasonable to assume that a relatively strong donor–acceptor bond arises between the reagents [13].

## Conclusion

The results of the study of kinetic regularities in the process synthesis of 2-hydroxyethyl-1,3,4trimethylcyclohexa-3-ene-1-carboxylate and the study of the mechanism of this reaction showing its corresondence to the Michaelis-Menten equation confirm the formation of an intermediate complex between the reagents, 2,3-dimethylbuta-1,3-diene and 2-hydroxyethylmethacrylate. The study of thermodynamic parameters of formation of the intermediate complex suggests that the limiting stage is the slow formation of an intermediate complex, the activation parameters of the transformation of the intermediate complex in the product indicates that the conversion of the intermediate complex in the product occurs rapidly and spontaneously.
